

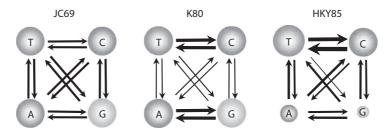

**Fig. 1.1** Illustration of multiple substitutions at the same site or multiple hits. An ancestral sequence has diverged into two sequences and has since accumulated nucleotide substitutions independently along the two lineages. Only two differences are observed between the two present-day sequences, so that the proportion of different sites is  $\hat{p} = 2/8 = 0.25$ , while in fact as many as 10 substitutions (seven on the left lineage and three on the right lineage) occurred so that the true distance is 10/8 = 1.25 substitutions per site. Constructed following Graur and Li (2000).

**Fig. 1.2** Relative substitution rates between nucleotides under three Markov chain models of nucleotide substitution: JC69, K80, and HKY85. The thickness of the lines represents the substitution rates, while the sizes of the circles represent the steady-state distribution.
